The Search for George DeBaptiste’s House: The Crooked Creek Flood of 1846

Christopher Baas and Darrin L. Rubino

Summary

We used archival sources and Geographic Information Systems data to demonstrate the feasibility of the 1846 Crooked Creek Flood (Madison, Indiana, USA) having destroyed the home connected to abolitionist and Underground Railroad leader George DeBaptiste.

George DeBaptiste (1814–1875) was an African American abolitionist and a prominent figure in the Underground Railroad (UGRR), the network used by African American slaves in the Southern US to escape to free Northern states. He resided in Madison, Indiana, between 1838 and 1846, when he moved his family to Detroit, Michigan, following local race riots against UGRR leaders. In an effort to preserve the heritage of this icon’s legacy, preservationists used historical documentation to determine the likely location of DeBaptiste’s house. We performed tree-ring analysis to confirm if the existing house on the property was, in fact, DeBaptiste’s house. Determining the construction date of a structure using tree rings is performed by obtaining samples from a structure’s timbers and matching their tree-ring growth patterns to regional historic growth patterns. Analysis showed that the structure’s timbers were harvested sometime after the spring of 1846. These results were puzzling since DeBaptiste left Madison in 1846. It is unlikely that DeBaptiste would have constructed a new structure while racial tensions were reaching a fever pitch. Investigating Madison’s history provided a potential clue.
On 3 September 1846 the Crooked Creek Flood devastated the northern sections of Madison. The *Madison Republic* reported the horrific event. A two-hour rainstorm caused “mad waters to come tumbling down from every hollow,” converting Crooked Creek “into a lake or broad river.” Witnesses reported how “houses, animals, fences, barrels, and all kinds of household furniture, came whirling along, like bubbles.” The debris “choked” the Madison, Indianapolis & Lafayette railroad culvert, ultimately impounding water “so as to cover the whole space... north of the city to the hills beyond.” When the embankment failed, the “torrent” swept away a section of the railroad embankment, opening a 100-meter gap. Eleven people died; several were “swept off with their dwelling.” An 1871 oral history of the flood describes how house and bridge sites upstream and within 180 meters of the DeBaptiste house were destroyed. Dugan Hollow, a tributary of Crooked Creek upstream from the house site, dumped stormwater into the creek, fueling the destruction.

Could the flood explain why we found a house constructed in 1846 rather than one built concurrently with or prior to DeBaptiste’s time in Madison? We were puzzled by how DeBaptiste’s home, more than 1.6 kilometers upstream from the railroad culvert, could have been affected by the storm and wondered if we could demonstrate that the flash flood destroyed his house. Madison was platted on a terrace between the Ohio River and bluffs that rise more than 100 meters above the town. Crooked Creek originates on the bluff tops, runs between the base of the bluffs and the north side of the town, and empties into the Ohio immediately west of...
Madison. Branches of the creek, like Dugan Hollow, drain adjacent hills.

The Madison, Indianapolis & Lafayette Railroad is the state’s first railroad (1841), and infamous for its “incline,” a section of track with the steepest slope of any railroad in the country (412 meters rise over 2.1 kilometers of track). Construction required the removal of as much as 38 meters of limestone. To establish a consistent slope from the city to the bluff top, Crooked Creek valley was filled with nearly 21 meters of stone and soil; the creek was channeled in a culvert beneath the embankment.
With computer-aided technology, we tested a scenario where the railroad culvert clogs with debris to create a pool of water extending upstream to the DeBaptiste property. DEM data (1 meter resolution) was used in Geographic Information Systems Software to identify key elevations for the DeBaptiste property (149 meters representing 0.3 meters of floodwater on the property), the creek at the culvert (135 meters), and the top of the railroad embankment (155 meters, or 20 meters above the creek). We noted that DeBaptiste’s property is only 41 meters from, and 6 meters higher than, Crooked Creek. We acknowledged the limitations that historic accounts included little regarding water depth and that our current topographic data may not precisely replicate Madison’s 1846 landscape. We highlighted the house’s 149-meter contour elevation to see if a reservoir extended from the railroad culvert to the house site in the case that the culvert was closed. As a result, a 73-hectare pool is created that (like that described in the article from the Madison Republic) extends upstream beyond the house and the confluence with Dugan Hollow.
Map of Madison, Indiana showing the location of the railroad culvert and the DeBaptiste property. The white lines represent 10-meter contours and demonstrate how Madison was built on a riverside plateau adjacent to substantial bluffs. The dashed red line represents the 149 m contour line, which is the elevation of the DeBaptiste property and the elevation floodwaters would need to reach to affect buildings on the property.

Our test was able to demonstrate the severity of the disaster. Hypothetically, floodwater pools to a depth of 13 meters at the railroad embankment, and the reservoir extends to the DeBaptiste property (and 1.6 kilometers beyond). While the result of the study does not prove the house was lost in the disaster, it does suggest that if the initial flooding did not destroy the house, the flow from Dugan Hollow and the rush of floodwater following the breach in the embankment could have severely damaged the structure.

Combining tree-ring research, historical documents, and GIS software allowed us to hypothesize the fate of George DeBaptiste’s Madison home. The house historians sought to preserve, though found on DeBaptiste’s former property, was likely built once Crooked Creek and its tributaries returned to their banks.

About the authors:

Christopher Baas
Christopher Baas is an associate professor in the Department of Landscape Architecture at Ball State University and a registered landscape architect. He earned his BLA at Ball State University and his master’s at the University of Wisconsin–Madison. Christopher’s scholarly focus is documenting and interpreting historic cultural landscapes.
Darrin L. Rubino
Dr. Darrin L. Rubino is a Professor of Biology at Hanover College. He is a graduate of Thiel College, earned his Masters from Clarion University of Pennsylvania, and Ph.D. from Ohio University. His main research interest is dendrochronology, the study of tree-rings. He uses patterns of tree rings to understand the influence of historic human impacts and natural processes on forest structure, function, and composition.
