

The North Sea Flood of 1953

Alexander Hall

Summary

The North Sea flood of 1953 caused widespread damage and fatalities in the UK, the Netherlands, and Belgium. The coastal flooding was caused by the combination of an extreme extratropical storm and high spring tides, resulting in a storm surge of over 3 meters passing south across the North Sea. The surge devastated the east coast of England and large swathes of the Netherlands. Across the afflicted countries, over 2,000 square kilometers of land was flooded and approximately 2,400 people lost their lives.

The floods were responsible for triggering many changes in how the countries surrounding the North Sea manage their flood risk, including the development of improved warning systems, the building of the British Thames Barrier and the extensive Dutch Delta Works, which includes dams, sluices, locks, dikes, levees, and storm surge barriers.

Despite a gale warning from the local meteorological office on the morning of Saturday, 31 January 1953, the passenger ferry *Princess Victoria* left Stranraer, Scotland for her regular journey across the Irish Sea. Shortly after departure, the ship got into trouble, and at 2 p.m., before rescue crews could locate the listing vessel, the order was given to abandon ship. Of her 179 passengers and crew, 133 lost their lives.

Netherlands. Viewed from a US army helicopter, a Zuid Beveland town gives a hint of the tremendous damage wrought by the flood to Dutch islands.

The *Princess Victoria* was the first victim of an exceptional European windstorm, an extreme extratropical cyclone that grew in intensity as it skirted the British Isles and veered south along the east coast of Great Britain, with devastating effects. The storm coincided with high spring tides and the semi-enclosed shape and shallowness of the North Sea to produce a storm surge that flooded large swathes of the east coast of England, the Netherlands, and parts of Belgium. The surge peaked at 3.35 meters above the average sea level, and waves of over 4.9 meters were recorded. In the countries affected, physical sea defenses were in a dilapidated state due to the Second World War, and warning systems, where they existed, were rudimentary. In the UK there was no national warning system in place and so, despite the earlier sinking of the *Princess Victoria* and the slowness of the southward progression of the storm surge, each community along the coast was inundated unexpectedly as they slept. The Dutch storm tide warning service was more advanced than in the UK, but despite warnings being distributed widely via telegram and radio, the occurrence of the flood during the middle of the night, when the radio stations were not broadcasting and people were asleep, rendered the warnings almost useless.

Extent of the flooding on the east coast of England

The scale of the flooding was unprecedented. In England there were 1,200 breaches of sea defenses, 140,000 acres of land were flooded, 32,000 people were evacuated, 24,000 properties were damaged, 46,000 livestock were killed, and 307 people died. In the Netherlands, approximately 100,000 people were evacuated, 340,000 acres were flooded, 47,300 buildings were damaged, 30,000 livestock were killed, and 1,836 lives were lost. In addition, there were 17 deaths in Scotland, 22 in West Flanders, Belgium, and 230 in vessels at sea (including the 133 lost on the *Princess Victoria*).

The catastrophe led to in-depth government reviews of events in both the Netherlands and the UK, resulting in significant improvements in coastal defenses, warning systems, and flood management policy. In the UK, the largest results of this review process were the development of the Storm Tide Warning Service (today part of the National Severe Weather Warning System) and eventually the completion of the Thames Barrier in 1984 to protect London from future surges. In the Netherlands, the Delta Commission's study into the cause and effect of the floods led to the Delta Works, a series of dams, locks, sluices, levees, and storm surge barriers, including the nine-kilometer Oosterscheldekering dam, that now protect the Netherlands from the threat of coastal flooding.
