

Winter Water and Mobility in Early Modern Amsterdam

Bob Pierik

Summary

During the Little Ice Age's many harsh winters, frozen waterways posed challenges and opportunities in Holland, in the west of the Dutch Republic. Focusing on Amsterdam, this contribution considers how harsh winters transformed mobility. The frozen waterways disrupted infrastructure—for instance, by complicating the import of clean drinking water on barges. Simultaneously, the ice allowed for other types of mobility, as a “slipping and sliding society” appeared seasonally.

In January 1763, chronicler Jacob Bicker Raije wrote that the ice in Amsterdam that winter was so thick that even the icebreaker could not sail. “Fresh water is so scarce that [prices rise] and water has to be brought in by sledge and horse from Muiden and Weesp. Many people use the ice from the IJ [(estuary)], Amstel [(brackish river)], and even the canals, which causes many illnesses.”

As a result of the relatively colder climate regime that we have come to know as “the Little Ice Age,” the Dutch Republic endured severer winters in the early modern period. In its western province of Holland, where most vital transport infrastructure was water-based and the winter temperature lingered around freezing point, the Little Ice Age’s average one-degree difference in temperature compared to the twentieth century could mean the waterways froze for weeks or even months—rather than a few days a year. In this contribution, I consider some of the effects of the seasonal transformation of water to ice as they relate to mobility. By looking at frozen waterways and drinking water, I seek to show how mobility is a fruitful framework for environmental histories even before the fossil-fuel-powered mobility revolutions.

Slipping and sliding—mobility on the frozen Amstel. Detail from Jacob Cats, *Gezigt van de kom, tusschen de Doeplestraat en de Halvemaan's Brug*, 1783.

Access to drinking water became a problem in harsh winters. Keeping water unfrozen and pumps working was a substantial effort, requiring a great deal of labor and fuel. While many other early modern European cities were serviced by wells and rivers, many cities in coastal Holland had their drinking water supplied by means of rainwater cisterns and imported surface water because the local surface and ground water was too brackish to drink. Mobility thus plays an important role here: in Amsterdam, surface water had to be imported from further upstream by barges, as there was no conduit or aqueduct. This barge-imported water was also used to fill cisterns in severe winters. The Amsterdam brewers together maintained a horse-pulled icebreaker to break open the ice in the winter and secure the route upstream to good water. Yet, while water selling has previously been described mostly as a side activity of these brewers, notarial deeds show a larger industry of water sellers who kept staff and sold water by the bucket from floating wooden containers in the canals: in 1765, water seller Trijntje van Rosmalen was busy freeing her water container from ice with three additional people (see also Figure 1), when she was bothered by the son of a water importer that she had previously bought her water from (she now bought her water from another importer). The notarial deposition shows water imports were a larger industry and infrastructure than merely a brewers' side activity—and that ice and frost presented significant challenges to it.

While harsh winters disrupted mobility and could cause scarcity of drinking water, snow and ice also brought

along new types of mobility and heralded a “slipping and sliding society”—that could be both leisurely and lethal. In Amsterdam, seventeenth-century regulations against nuisance from snow sleds drawn by horses show that the strict management of vehicular speed in the city was uniquely challenged by the ease of speeding in the snow or on the ice. Bicker Raije wrote in January 1771 that “as it has snowed heavily for some days, lovers of snow sleds can be very happy. This morning from 10.00 to 13.30 and from 15.00 to 16.30, I have myself counted 357 horse-drawn snow sleds that passed my house.” These are high numbers, considering that the sleigh-man’s guild had 285 sleigh-men that serviced the whole of the city of Amsterdam with land sleds all year round. These were sleighs that normally could not go very fast on the cobbled streets, which kept the infrastructural system in order. Yet, the sleighs could speed up considerably in the winter, as sleigh-men illegally threw water onto the streets in order to create an icy surface. Similarly, the ice allowed for another illegal type of mobility: in 1717, a witness attested in front of the chief officer of the city that he had seen people illegally entering and leaving the city without properly going through the gates, instead crossing the frozen fortification canals.

Stepping on the ice was not without its dangers. While a sizable number of people already drowned in the canals outside of the winter, the ice, frost, and fog further increased the water’s lethality. One could slip and fall through a crack or hole in the ice and get caught underneath it, in the freezing water. Bicker Raije meticulously reported drownings throughout the year. Looking at all drownings in and directly around Amsterdam (excluding suicides and murders) that he reported in his chronicle in the period 1732–1772, I found 81 incidents, in which a total of 212 people were reported drowning. While instances of drowning were roughly distributed throughout the year, the high numbers of people drowning in January and November specifically make the fall and winter

stand out. These higher numbers were driven by several specific events with multiple fatalities, such as on 13 January 1738, when Bicker wrote that 43 drowned people were found under the ice. On 22 November 1740, Bicker recorded that at least 28 people had drowned because of heavy fog. In total, 61 people drowned in cases in which Bicker explicitly mentioned ice or frost and for 69 people he mentioned fog, together comprising more than half of all the drowned people he reported.

	<i>Instances of drowning</i>		<i>People drowning</i>	
<i>Spring (Mar, Apr, May)</i>	20	24,7%	29	13,7%
<i>Summer (Jun, Jul, Aug)</i>	16	19,8%	16	7,5%
<i>Autumn (Sep, Oct, Nov)</i>	21	25,9%	67	31,6%
<i>Winter (Dec, Jan, Feb)</i>	24	29,6%	100	47,2%

All in all, the wintery transformation of Amsterdam's watery infrastructures created seasonal types of mobility that posed both challenges and opportunities, with fun on sleighs for some, but also water scarcity and a higher danger of drowning for others.

About the author:

Bob Pierik

Bob Pierik is a postdoctoral researcher at VU Amsterdam. As a historian of everyday life, he focuses on capturing social and cultural life as expressed in practices, through which he studies gender, mobility, women's work, vehicles, and most recently water use. His 2022 dissertation, "Urban Life on the Move: Gender and Mobility in Early Modern Amsterdam," was published in Dutch as *Zo veel leven voor de deur* in 2023.
